Output window

```
140000004: using guessed type __int64 sub_140000004(vol2);  
14000000C: using guessed type __int64 _fastcall sub_14000000C_(QWORD, QWORD, QWORD, QWORD);  
Python AU: idle Down Disk: 200B
```

可以判断出，这个程序实际上是由Python打包成的可执行文件，且在运行这个程序时，在同目录下产生了一个tmp.dll文件，猜测是程序调用某些函数的接口。

## 反编译

使用archive\_viewer.py反编译为字节码文件

```
python archive_viewer.py signin.exe
```

```
(38002548, 935, 2406, 1, 'x', 'tk\\ttk\\\\sizegrip.tcl'),  
(38003483, 1510, 4255, 1, 'x', 'tk\\ttk\\\\spinbox.tcl'),

程序是在Python3.8环境下打包，因此我们需要在Python3.8下使用uncompyle6

```
uncompyle6 main.pyc > main.py
```

得到py文件

```
1 # uncompyle6 version 3.7.2
2 # Python bytecode 3.8 (3413)
3 # Decompiled from: Python 3.8.0 (tags/v3.8.0:fa919fd, Oct 14 2019, 19:37:50) [MSC v.1916 64 bit (AMD64)]
4 # Embedded file name: main.py
5 # Compiled at: 1995-09-28 00:18:56

## 代码分析

通过代码我们能够了解到这些信息

1.

```
elf.dllname = './tmp.dll'
```

调用了tmp.dll文件作为接口。

2.

```
self.accounts = {b'SCTFer': b64decode(b'PLHCu+fujfZmMOMLGHCyWWoq5H5HDN2R5nHn1V30Q0EA')}
```

调用tmp.dll文件中的enc函数，传入username, password, pwd\_safe, len(pwd\_safe)，实际就是将password加密后存储到pwd\_safe字节码中。最后用pwd\_safe与b64decode(b'PLHCu+fujfZmMOMLGHCyWWOq5H5HDN2R5nHnIV30Q0EA')比较，且我们能够了解到用户名应该是SCTFer，且最后返回的status一个为非1。

打开tmp.dll文件，找到enc函数

```

16 const char *Str; // [rsp+1D8h] [rbp+1B8h]
17 _int64 v19; // [rsp+1E0h] [rbp+1C0h]
18 int v20; // [rsp+1E8h] [rbp+1C8h]
19
20 v20 = a4; // pwd_safe长度
21 v19 = a3; // pwd_safe
22 Str = a2; // password
23 v17 = a1; // username
24 v4 = &v9;
25 for ( i = 110i64; i; --i )
26 {
27     *_DWORD *v4 = -858993460;
28     v4 += 4;
29 }
30 sub_180011078((__int64)&unk_180020003); // 密码长度
31 v10 = j_strlen(Str); // 用户名长度
32 v11 = j_strlen(v17);
33 if ( v10 <= v20 )
34 {
35     while ( v10 < 32 )
36         Str[v10++] = 0;
37     v12 = 0;
38     for ( j = 0; j < 4; ++j ) // 循环4次
39     {
40         _mm_lfence();
41         memset(&Dst, 0, sizeof(Dst));
42         j_memcpy(&Dst, &Str[v12], 8ui64); // 每次给Dst传入password的8字节数据
43         Dst = sub_180011311(Dst); // 加密函数
44         j_memcpy((void *)(v12 + v19), &Dst, 8ui64);
45         v12 += 8;
46     }
47     for ( k = 0; k < 32; ++k ) // 数据异或
48     {
49         v16 = k;
50         *(__BYTE *)(v19 + k) ^= v17[k % v11];
51     }
52     *(__BYTE *)(v19 + 32) = 0;
53     v6 = 0i64;
54 }
55 else
56 {
57     v6 = 1i64;
58 }
59 v7 = v6;
60 sub_18001131B(&v9, &unk_18001A4A0);
61 return v7;
62 }

```

观察代码，实际操作可以分为两部分，逆向分析

## 异或操作

第47~54行代码实际上就是将Dst与用户名循环异或，最后得到

b64decode(b'PLHCU+fujfZmMOMLGHCyWWOq5H5HDN2R5nHnIV30Q0EA')，因此我们只需要逆向异或就能得到加密后的Dst

```

from base64 import *

username = "SCTFer"
pwd_safe = b64decode('PLHCu+fujfZmMOMLGHCyWw0q5H5HDN2R5nHn1V30Q0EA')
# print (len(pwd_safe))
num = ["%02x" % x for x in pwd_safe]
hex_num = [int(x, 16) for x in num]

print(num)
# print (len(num))
for i in range(32):
    hex_num[i] ^= ord(username[i % len(username)])
# print (hex_num)
hex_nums = bytes.fromhex('.join([hex(x)[2:]:rjust(2, '0') for x in hex_num])))

print (hex_nums)

```

得到

b'0\xf2\x96\xfd\x82\x9c\xde\xb52v\x86yK3\xe6\x1f\x06\xd8\xb7=\x13J\xb8\xe3\xb52\xb3\xd38\x86\x10\x02\x00'

## 加密操作

每次传入了8字节数据进行加密（总共64字节），打开sub\_180011311函数

```

1 int64 __fastcall sub_180011311(int64 a1)
2 {
3     _int64 *v1; // rdi
4     signed _int64 i; // rcx
5     _int64 v4; // [rsp+0h] [rbp-20h]
6     int j; // [rsp+24h] [rbp+4h]
7     _int64 v6; // [rsp+120h] [rbp+100h]
8
9     v6 = a1;
10    v1 = &v4;
11    for ( i = 66i64; i; --i )
12    {
13        *(DWORD *)v1 = -858993460;
14        v1 = (_int64 *)((char *)v1 + 4);
15    }
16    sub_180011078((int64)&unk_180020003);
17    for ( j = 0; j < 64; ++j )
18    {
19        if ( v6 >= 0 )
20            v6 = sub_18001130C(2 * v6);
21        else
22            v6 = sub_18001130C(2 * v6 ^ 0xB0004B7679FA26B3ui64);
23    }
24    return v6;
25 }

```

仔细观察代码，实际上这部分代码是使用CRC32的查表法，对数据进行加密。

加密原理实际上就是CRC32算法---输入一组长度32的字符串，每8个字节分为1组，共4组。对每一组取首位，判断正负。正值，左移一位；负值，左移一位，再异或0xB0004B7679FA26B3。重复判断操作64次，得到查表法所用的表。

因此我们只需要将整个加密过程逆向操作得到查表法的表，再进行CRC32计算，就能得到输入。

```

secret = []

# for i in range(4):
#     secret.append(int(hex_nums[i*8:(i + 1) * 8][::-1].hex(),16))

for i in range(4):
    secret.append(int.from_bytes(hex_nums[i*8:(i + 1) * 8], byteorder="little"))

print (secret)

key = 0xB0004B7679FA26B3

flag = ""

for s in secret:
    for i in range(64):
        sign = s & 1
        if sign == 1:
            s ^= key
        s //= 2
        if sign == 1:
            s |= 0x8000000000000000
    print(hex(s))
j = 0
while j < 8:
    flag += chr(s&0xFF)
    s >>= 8
    j += 1
print(flag)

```

因为计算机中采用小端排序，因此需要注意分组倒序。得到

```

[13105084052108931695, 2298581059073635890, 16408946688824694790, 148766366331253429]
0x3165577b46544353
0x5f6f545f336d3063
0x3230325f66746353
0x7d21215f65725f30
SCTF{Welc0m3_To_Sctf_2020_re_!!}

```

## 脚本

```

from base64 import *

username = "SCTFer"
pwd_safe = b64decode('PLHCu+fujfZmMOMLGHCyWw0q5H5HDN2R5nHn1V30Q0EA')
# print (len(pwd_safe))
num = ["%02x" % x for x in pwd_safe]
hex_num = [int(x, 16) for x in num]

print(num)
# print (len(num))
for i in range(32):
    hex_num[i] ^= ord(username[i % len(username)])
# print (hex_num)
hex_nums = bytes.fromhex(''.join([hex(x)[2:]:rjust(2, '0') for x in hex_num]))

print (hex_nums)

secret = []

# for i in range(4):
#     secret.append(int(hex_nums[i*8:(i + 1) * 8][::-1].hex(),16))

for i in range(4):
    secret.append(int.from_bytes(hex_nums[i*8:(i + 1) * 8], byteorder="little"))

print (secret)

key = 0xB0004B7679FA26B3

flag = ""

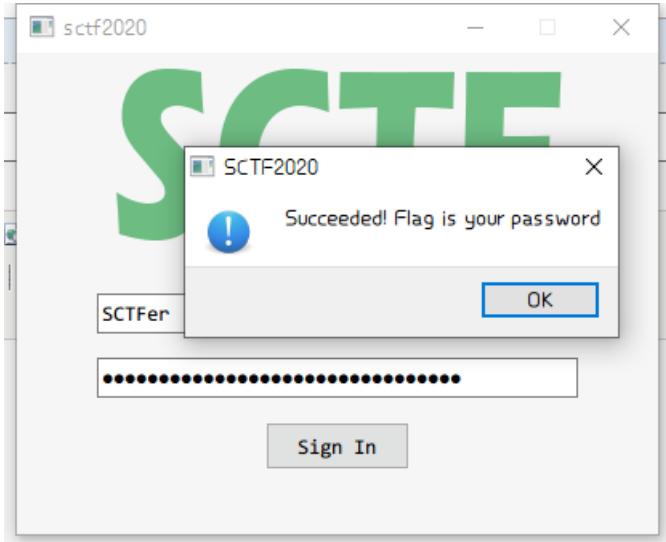

for s in secret:
    for i in range(64):
        sign = s & 1
        if sign == 1:
            s ^= key
        s //= 2
        if sign == 1:
            s |= 0x8000000000000000
    print(hex(s))
    j = 0
    while j < 8:
        flag += chr(s&0xFF)
        s >>= 8
        j += 1
print(flag)

```

**get flag!**

username:SCTFer

password:SCTF{We1c0m3\_To\_Sctf\_2020\_re\_!!}

## get\_up

```
1 void sub_402700()
2 {
3     char *v0; // ST14_4
4     HMODULE lpAddress; // ST18_4
5     DWORD f1OldProtect; // [esp+Ch] [ebp-14h]
6     char Dst; // [esp+10h] [ebp-10h]
7
8     printf("you should give me a word:");
9     memset(&Dst, 0, 0xAu);
10    scanf_s("%s", &Dst, 10);
11    if ( strlen(&Dst) > 6 || !sub_401DF0(&Dst) )
12    {
13        sub_401080(std::cout, "try again");
14        exit(0);
15    }
16    v0 = sub_402B00(".reloc");
17    lpAddress = GetModuleHandleW(0) + (*((DWORD *)v0 + 3) >> 2);
18    VirtualProtect(lpAddress, *((_DWORD *)v0 + 4), 0x40u, &f1OldProtect);
19    sub_402610((int)lpAddress, &Dst);
20 }
```

这是实际就是在说明输入字符串长度不大于6，且通过sub\_401DF0返回1

```

1 char __cdecl sub_401DF0(char *Str)
2{
3     char result; // al
4     size_t Size; // [esp+Ch] [ebp-90h]
5     signed int i; // [esp+14h] [ebp-88h]
6     signed int j; // [esp+14h] [ebp-88h]
7     char v5; // [esp+18h] [ebp-84h]
8     char Str2; // [esp+30h] [ebp-6Ch]
9     char Dst; // [esp+54h] [ebp-48h]
10    char v8[39]; // [esp+55h] [ebp-47h]
11    unsigned __int8 v9[16]; // [esp+7Ch] [ebp-20h]
12    int v10; // [esp+98h] [ebp-4h]
13
14    Size = strlen(Str);
15    for ( i = 0; i < 1000000; ++i )
16        sub_402C90(Str, Size, (int)v9);
17    memset(&Dst, 0, 0x28u);
18    sub_4015C0("0123456789abcdef");
19    v10 = 0;
20    for ( j = 0; j < 16; ++j )
21    {
22        *(&Dst + 2 * j) = *(_BYTE *)sub_4019A0((signed int)v9[j] >> 4);
23        v8[2 * j] = *(_BYTE *)sub_4019A0(v9[j] % 16);
24    }
25    printf("\n");
26    strcpy(&Str2, "32c1d123c193aecc4280a5d7925a2504");// sycsyc
27    if ( !strcmp(&Dst, &Str2) )
28    {
29        v10 = -1;
30        std::basic_string<char, std::char_traits<char>, std::allocator<char>>::~basic_string<char, std::char_traits<char>, std::allocator<char>>(&v5);
31        result = 1;

```

返回1，实际就是满足加密后的Dst与32c1d123c193aecc4280a5d7925a2504相同，实际是MD5加密，得到输入为sycsyc

接下来，程序查找.reioc段，并将.reioc段数据与sycsyc循环异或，写出IDAPython脚本

```

beg_adr = 0x405000
dst = "sycsyc"
for i in range(0,0x200,16):
    for j in range(16):
        PatchByte(beg_adr+i+j,Byte(beg_adr+i+j)^ord(dst[j%6]))

```

然后跟去混淆方法类似，先转换为Data，再强制分析数据，转换为函数。

```

1 int sub_405000()
2{
3     sub_403120();                                // flag plz!
4     return sub_4027F0();
5 }

```

打开sub\_4027F0函数

```

1 void sub_4027F0()
2 {
3     char *v0; // ST18_4
4     HMODULE lpAddress; // ST1C_4
5     signed int i; // [esp+10h] [ebp-40h]
6     DWORD f1OldProtect; // [esp+14h] [ebp-3Ch]
7     char Dst[40]; // [esp+18h] [ebp-38h]
8     char Str[12]; // [esp+40h] [ebp-10h]
9
10    memset(Dst, 0, 0x28u);
11    memset(Str, 0, 0xAu);
12    scanf_s("%s", Dst, 40);
13    if ( strlen(Dst) != 30 )           // flag长度为30
14    {
15        sub_401080(std::cout, "try again");
16        exit(0);
17    }
18    for ( i = 0; i < 5; ++i )
19        Str[i] = Dst[i];
20    v0 = sub_402B00(".ebata");
21    lpAddress = GetModuleHandleW(0) + (*((DWORD *)v0 + 3) >> 2);
22    VirtualProtect(lpAddress, *((DWORD *)v0 + 4), 0x40u, &f1OldProtect);
23    sub_4025B0((int)lpAddress, Str);
24    sub_404000();
25}

```

这里实际和上面差不多，输入长度为30的flag，取前5个字符，与.ebata段的部分循环异或。（实际就是得到下面sub\_404000函数的代码）。这里可以合理猜测flag的前五个字符为**SCTF{**,写出脚本

```

beg_addr = 0x404000
dst = "SCTF{"
for i in range(16,96):
    PatchByte(beg_addr+i,Byte(beg_addr+i)^ord(dst[i%5]))

```

跟上面一样将.ebata段转换为data，再分析代码，转换为函数，开头如果提示栈不平衡，重新单独分析一下就行。

```

13 char v12; // [esp+99Dh] [ebp-Fh]
14 char v13; // [esp+99Eh] [ebp-Eh]
15 char v14; // [esp+99Fh] [ebp-Dh]
16 char v15; // [esp+9A0h] [ebp-Ch]
17 char v16; // [esp+9A1h] [ebp-Bh]
18 char v17; // [esp+9A2h] [ebp-Ah]
19 char v18; // [esp+9A3h] [ebp-9h]
20 char v19; // [esp+9A4h] [ebp-8h]
21
22 v11 = 's';
23 v12 = 'y';
24 v13 = 'c';
25 v14 = 'l';
26 v15 = 'o';
27 v16 = 'v';
28 v17 = 'e';
29 v18 = 'r';
30 v19 = 0;
31 memset(Dst, 0, 0x28u);
32 for ( i = 0; i < strlen(Str); ++i )
33     Dst[i] = Str[i];
34 for ( j = 0; (signed int)j < 256; ++j )
35 {
36     v9[j] = j;
37     v1 = strlen(&v11);
38     v3[j] = *(&v11 + j % v1);
39 }
40 v5 = 0;
41 for ( k = 0; k < 256; ++k )
42 {
43     v5 = (v3[k] + v9[k] + v5) % 256;
44     v4 = v9[k];
45     v9[k] = v9[v5];
46     v9[v5] = v4;
47 }
48 return sub_401A70((int)v9, Dst);
49}

```

这里一个函数实际就是RC4生成S-BOX，另一个函数就是加密函数，key值为syclover

```

#include<stdio.h>
#include<stdlib.h>
#include<string.h>
typedef unsigned long ULONG;

#pragma warning(disable:4996)

/*初始化函数*/
void rc4_init(unsigned char* s, unsigned char* key, unsigned long Len)
{
    int i = 0, j = 0;
    char k[256] = { 0 };
    unsigned char tmp = 0;
    for (i = 0; i < 256; i++)
    {
        s[i] = i;
        k[i] = key[i % Len];
    }
    for (i = 0; i < 256; i++)
    {
        j = (j + s[i] + k[i]) % 256;
        tmp = s[i];
        s[i] = s[j]; // 交换s[i]和s[j]
        s[j] = tmp;
    }
}

/*加解密*/
void rc4_crypt(unsigned char* s, unsigned char* Data, unsigned long Len)
{

```

```

{
    int i = 0, j = 0, t = 0;
    unsigned long k = 0;
    unsigned char tmp;
    for (k = 0; k < Len; k++)
    {
        i = (i + 1) % 256;
        j = (j + s[i]) % 256;
        tmp = s[i];
        s[i] = s[j]; // 交换s[x]和s[y]
        s[j] = tmp;
        t = (s[i] + s[j]) % 256;
        Data[k] ^= s[t];
    }
}

int main()
{
    unsigned char s[256] = { 0 }, s2[256] = { 0 }; // S-box
    char key[256] = { "syclover" };
    char pData[512] = { 0 };
    int v12[] = { 128,85,126,45,209,9,37,171,60,86,149,196,54,19,237,114,36,147,178,200,69,236,22,107,103,2
    int i;
    //char m[32] = { 0 };

    for (int i = 0; i < 30; ++i) {
        pData[i] = (char)v12[i];
    }

    unsigned long len = strlen(pData);

    printf("pData=%s\n", pData);
    printf("key=%s,length=%d\n\n", key, strlen(key));
    rc4_init(s, (unsigned char*)key, strlen(key)); // 已经完成了初始化
    printf("完成对S[i]的初始化, 如下: \n\n");
    for (i = 0; i < 256; i++)
    {
        printf("%02X", s[i]);
        if (i && (i + 1) % 16 == 0)putchar('\n');
    }
    printf("\n\n");
    for (i = 0; i < 256; i++) // 用s2[i]暂时保留经过初始化的s[i], 很重要的！！！
    {
        s2[i] = s[i];
    }

    printf("已经初始化, 现在解密:\n\n");
    printf("len = %d\n", len);
    rc4_crypt(s, (unsigned char*)pData, len);
    printf("pData=%s\n\n", pData);

    system("PAUSE");
    return 0;
}

```

```
bData=€U~-%?V磥6L蘂$境峯?kg□ 棒  
key=syclover, length=8
```

完成对S[i]的初始化，如下：

```
315052C1CDA707393D04FDC42A72DF60  
E3BDE261E463EAFFFEB09F9C3CE9E256A  
4CDC13F0833B24DBDD7FEF8C3EE1266F  
9206F796D0B4E7F85F78F2AA4432365A  
ECA67B08C02E9B84559CAE650A105388

542F3C6238FB820E3A195DB64020CC00
```

已经初始化，现在解密：

```
len = 30
```

```
bData=SCTF{zzz~(|3[___]_rc4_5o_e4sy)}
```

请按任意键继续. . .

```
SCTF{zzz~(|3[___]_rc4_5o_e4sy)}
```

## Can you hear

音频文件： <https://www.lanzous.com/iMv4zecuw3g>

音频是SSTV，用软件Robot36接受音频中的数据

## doudizhu

只要将手里牌出完，就能获得flag
